

Acquisition Research Program: Creating Synergy for Informed Change

Advanced Capability Builds for Aegis: Stochastic Portfolio Optimization (Selection and Prioritization), Risk Simulation, KVA, and Strategic Real Options

Introduction and Context

- **Introduction of Open Architecture (OA) business and technical processes provides opportunity to improve acquisition**
 - Increased competition
 - Shorter cycle time
 - Reduced total ownership and acquisition cost
- **The AEGIS Advanced Capability Build (ACB) process is one implementation of the OA approach**

The ACB Process

- The ACB process provides for software updates to ships within the program on a two-year cycle
- ACBs are identified by the first year in which they will be fielded, e.g., ACB-14
- US Navy CGs and DDGs will be inducted into the process as they receive computing plant updates during major availabilities that convert the processors and networks to a COTS-based configuration
- The hardware baseline that supports OA must be in place to begin execution of the ACB process
- Once a ship is inducted, it will receive the scheduled update plus any previous updates (e.g., ACB 16 ships entering the program will receive ACB 14 capabilities as well)

The problem addressed in this study deals with risk and value

- Value is realized through fielding of military capability for the war-fighter
- Risk is found in uncertainty
 - Cost uncertainty creates budget risk
 - Technology risk can lead to schedule and budget risk
- This study provided a pilot implementation of the Knowledge Value Added + Integrated Risk Management method to represent value and risk to assist the PM and sponsor in selecting the proper capability mix to field in a given ACB
- The problem space considered 23 capabilities to be implemented through changes to 32 software components across three scheduled ACBs (ACB 14, 16, and 18)
- Given the universe of desired capabilities, the problem is to select those providing the best value to the war-fighter for inclusion in a given ACB subject to budget constraints, risk and uncertainty of cost and timing

The study articulated a notional value of military value and used powerful financial and analytical tools

- Knowledge Value Added (KVA) provides ways of representing outputs (value) in common units
- Real Options provides tools to compare the value stream of various options in rigorous terms
- Integrated Risk Management considers uncertainties and represents risk in quantitative, clear and defensible terms

As ships enter the program and ACBs are executed, military value is additive

Aggregation of Relative EMV

One advantage of the ACB process is the “catch-up” effect

- The ACB process helps manage risk by allowing the PM and sponsor to delay introduction of a particular capability until it is ready without waiting many years for the next cycle
- A delay until the next ACB is more acceptable because within five years the number of ships with the capability will be the same

The remainder of this presentation discusses the analysis and results

- Assumptions and constraints
- Measurement of military value (KVA)
- Application of Real Options and Integrated Risk Management (IRM) to the selection of capabilities

Assumptions and Constraints

- The study applied the following initial assumptions
 - The capabilities were independent of each other
 - Capabilities were implemented through changes to modules within the objective architecture
- Initial constraints assumed
 - A notional **integration** budget of \$150 million per ACB
 - All uncertainty estimates for the initial model were based on cost volatility
- Future study will include
 - Effects of interdependencies (nested options), correlations, diversification
 - Schedule risk
 - Opportunity cost and penalty costs of abandonment

Measuring Value

- KVA **quantifies the value** of the knowledge used to produce common units of output
- Shows decision makers the **benefit and cost** of each program or project
- Measures how resources are allocated on the volatility of productivity (e.g., ROI)
- **Providing ROI volatility inputs to IRM**
- **Military value** in this study was postulated to be represented by capability provided to the warfighter measured in a variety of ways
 - Strategic importance as represented by OPNAV sponsor priorities
 - Technical value as represented by acquisition community priority
 - Functional complexity represented by Delivered Source Lines of Code (DSLOC)
 - Subject Matter Expert evaluation of complexity and mission criticality, aggregated from the component level

Integrated Risk Management Process

- 1** List of projects and strategies to evaluate

RISK IDENTIFICATION

Start with a list of projects or strategies to be evaluated... these projects have already been through qualitative screening

- 2** Base case projections for each project

RISK PREDICTION

...with the assistance of time-series forecasting, future outcomes can be predicted...

- 3** Develop static financial models

RISK MODELING

	Project 1	Project 2	Project 3	Project 4	Project 5	Project 6	Project 7	Project 8	Project 9	Project 10

KVA+RO+IRM are a combination of method and toolset to assist the PM in decision making

- Knowledge Value Added (KVA) is a method that systematically expresses non-revenue activities in common units of output to quantify value
- Real Options (RO) provides a way to qualitatively and quantitatively evaluate the relative value of various courses of action under consideration
- Integrated Risk Management combines KVA and RO with a powerful toolset to assist the program manager in the decision process
- Treatment of parameters as distributions permits rigorous analysis in an uncertain world, where instead of single point estimates, we use ranges as inputs
- Monte Carlo risk simulation and process models permit consideration of all possible outcomes within a reasonable time period
- Disciplined processes yield defensible results that can be updated as more knowledge/ information is realized by the program
- Risk simulation, sensitivity analysis, and forecasting are automated (analyses are efficient, quick, consistent, replicable, defensible, and scalable)

The toolset and method provide a way for the PM to determine the relative merits of the various options available, to make informed choices based on value streams and risk, and then to articulate those choices to the sponsor and the acquisition chain of command.

Model input assumptions are entered on a data sheet

Common sizing inputs and using weights to obtain the expected military value

Starting with 23 capabilities
(more to be added later
when there is sufficient data)

High, most likely, low cost
estimates for running
thousands of simulation trials

Technical and
OPNAV priorities

DSLOC provides a measure
of complexity

Intermediate computations: risk-
simulation assumption, readjusted
priorities, expected military score
and cost-based risk coefficients

Running the model provides recommended selections

ACB 14 sample results with \$150M budget constraint

Expected Military Value: SME Mean Value Added, DSLOC Complexity, Common Sized, Weighted OPNAV/Technical Priorities

Selection of EMV calculation method

Selection of EMV calculation method

Go or No-Go decisions in the portfolio selection

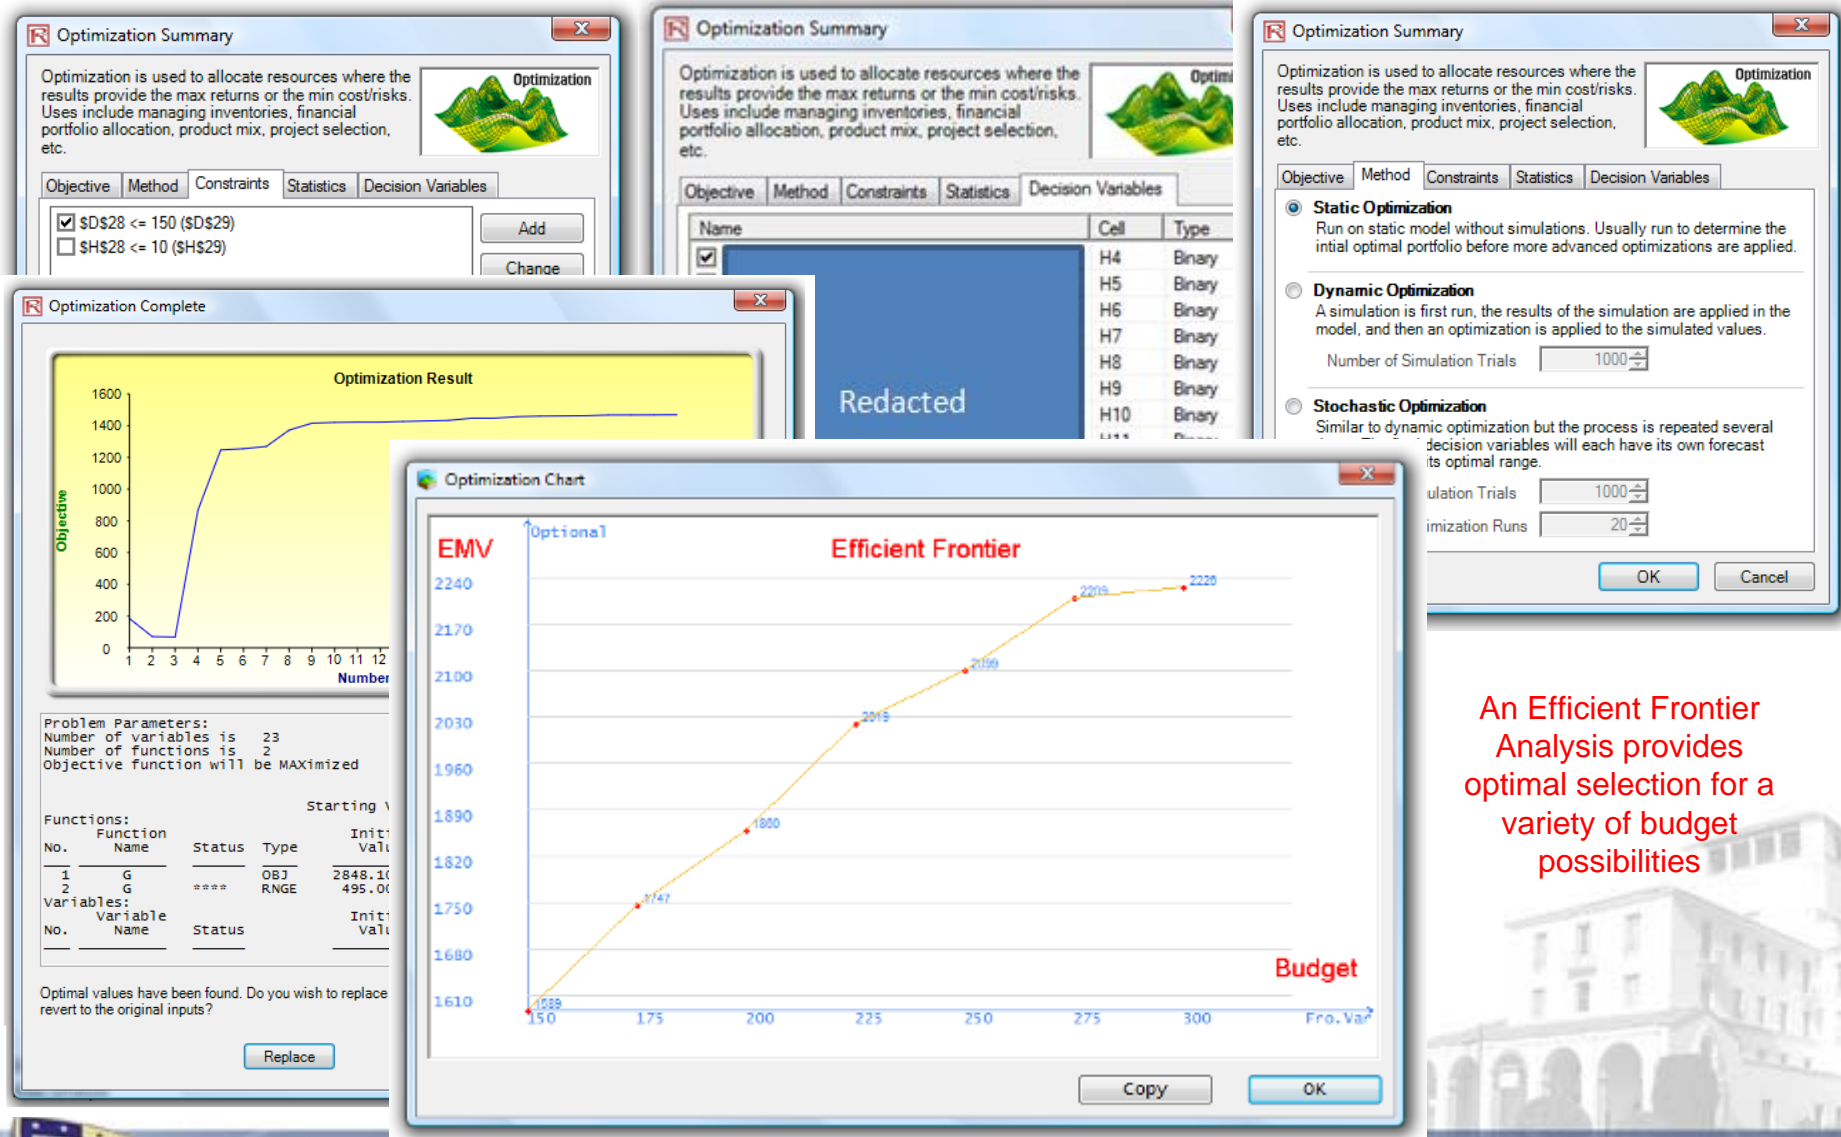

Benefits (EMV), Cost, Risk are considered

Constraints can be set (budget, capability count, FTE, priorities, etc)

Starting with 23 capabilities (more to be added later when there is sufficient data)

Portfolio optimization analysis gives a set of solutions

An Efficient Frontier Analysis provides optimal selection for a variety of budget possibilities

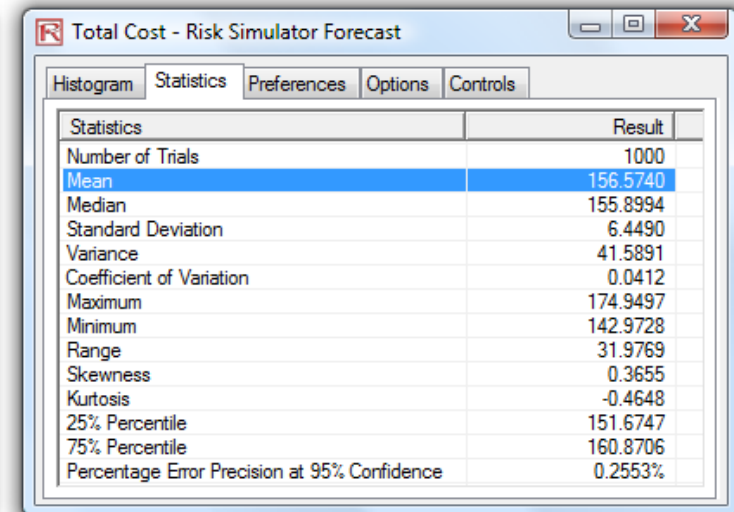

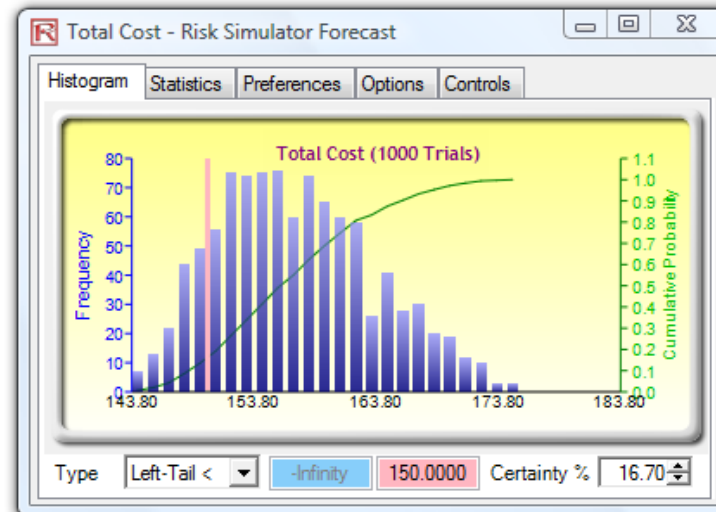

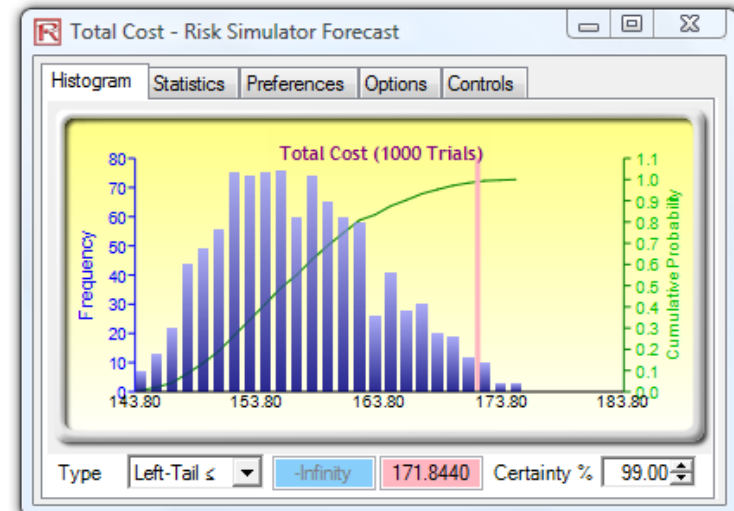

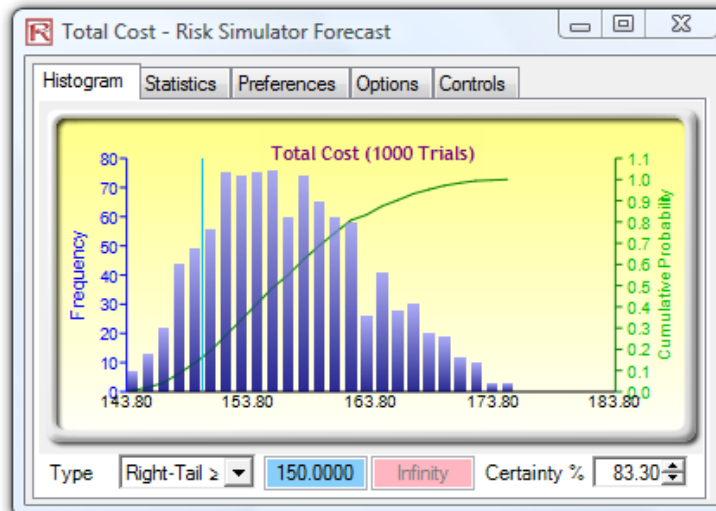

Risk simulation of cost provides the decision maker with additional data

Risk analysis and 100,000 simulation trials on cost estimations...

We can determine the probability that ACB-X will exceed the \$150M budget, determine what \$171M will yield a 99% certainty of sufficient budget to cover all costs

We also looked at the optimal portfolio given a 90% probability that \$150M will be enough

*Screen shots from Risk Simulator software

Optimized portfolios are time-sequenced and risks are quantified

More complex options and constraints can be accommodated in the analyses

Strategy Tree (Complex Multi-Stage Development)

In reality, an R&D project will yield intellectual property and patent rights that the firm can easily license off (Abandon). In addition, at any phase, the project's development can be slowed down (Contract) or accelerated (Expand) depending on the outcome of each phase.

Inclusion of Analysis of Alternatives or Courses of Action using strategic real options analysis of various implementation pathways, suitable for nested and path dependent options (some components and capabilities are interdependent)

- Risk can be mitigated or planned for though
 - Budgeting to the amount that the simulator reveals is necessary to provide a given level of risk
 - Improving cost estimate quality and reducing volatility
 - Up-front action to change the cost equation
 - Contractual limits on cost through use of fixed price or other contract vehicles to shift risk with the vendor
 - Incentives to the contractor that reward for success and penalize for failure to meet cost targets
- Capability selection can also be accomplished by applying risk constraints during the optimization

Going forward

- More complex analyses to determine which optimization portfolio to choose
 - nested and mutually exclusive options among and between various capabilities
 - expansion options of a base capability into additional capabilities
- Strategic real options approach to generate different implementation pathways
 - provide strategic option trees
 - identify best decision strategic option pathway
